

#CloudRING®

A distributed, open, and scalable hyperscale cloud platform unifies cloud service providers, developers, private cloud proprietors, edge telecom operators, and endpoint devices within a genuinely global peer-to-peer network. This network facilitates the delivery of services to end-users beyond the control of any single provider or jurisdiction, ensuring secure utilization of cloud technologies for client businesses without necessitating trust.

Traditional cloud market

Between 2018 and 2023, cloud usage experiences an 8.5-fold increase, outpacing other segments in growth.

Projection of the global cloud market volume (public services), 2018-2023, in billions of dollars.

Key trends in the global cloud market:

- **PaaS growth: 8.5X** – highlights the increasing demand for software development tools.
- **IaaS growth: 5X** – signifies the rising need for new computing and storage resources (compute & storage).
- **Continuous service and cybersecurity** – primary factors in the decision-making process for companies transitioning to the cloud.
- **Over 2/3 of companies intend to expand their investments in AI**, serving as a crucial driver for IaaS development.
- **Large enterprises** are adopting multi-cloud strategies to manage risk.
- **The EAEU cloud market** trails behind global market trends by over five years.

A mere 10% of the potential market has adopted cloud services

When discussing cloud services, it is important to recognize their diverse nature rather than treating them as a single, uniform entity. AWS, the leading cloud provider, is utilized by 1 million companies (or more accurately, users) out of a total of **333 million companies**. In general, it can be estimated that merely **around 3 million companies employ cloud services**, with the majority of these organizations having an IT infrastructure in place.

Cloud Computing Is Becoming More Common

Unresolved issues of ~~clients~~ partners

Cloud technologies have introduced a new way of building IT systems. The cloud has made it convenient to connect to shared pools of configurable computing resources and manage them simply and independently.

Drawbacks of modern clouds:

- Dependence on a single provider in a single jurisdiction (vendor lock-in)

Lack of trust in data processing by a third-party provider in a specific (or any) jurisdiction.

Reliance on human decisions concerning business and regulations.

Decision-making not always in the best interest of the client

- Lack of control over your IT (trust, but verify)

These are no longer your systems, even if installed in your data center.

Absence of a focus on verifiable algorithmic security and provable transparency.

- While a single cloud technology provider, as the center of a client's IT, strives to solve all IT problems, it cannot. One company cannot be an expert in all areas (Gazprom Neft Bazen platform, Medsi image analysis service, Self Driving Cloud platforms, Web3 technologies).

The development of a cloud vendor does not fully realize the potential of partners (all clients are partners).

The development of First Class Citizen services is only available to the vendor, while other developers are second-class citizens (imagine an OS where you cannot install applications – the out-of-the-box offering is sufficient for everyone) – the App Service Store model is ignored, as it was ignored by Microsoft in the PC market for decades (but there was the possibility of installing third-party applications in a non-standard way). The cloud is an operating platform for data centers, enabling the launch and sale of next-generation multi-user applications - services.

Technologies being developed are typically not available to other providers (especially in markets or audiences where there is no interest or opportunity for development now) – thousands of companies are developing the same things. Diversification should occur through added value – new service solutions and new ways of use.

Cloud technologies are not fully available in private data centers, including for a fee; large companies develop their own internal clouds (Tinkoff, Avito, MTS, Yandex, etc.) instead of developing solutions specifically tailored for them.

The capabilities of hybrid clouds are limited between providers, providers and private clouds, private clouds and partners (peer federations), and developers who create a fundamentally new channel for delivering cloud solutions. The local development of cloud services is complicated, and clients not yet using the cloud are not covered (cloud technologies can be used ubiquitously).

Instead of addressing the longstanding issues, cloud companies are "dealing with objections" out of concern for their business.

We are reinventing the cloud – separating the business and service provision from technology.

Humans are not perfect. Every 5-10 years, IT technologies used in the industry change almost completely. Today, we cannot predict how IT itself will change tomorrow. At the core of technology, there should be no immutable components.

We abstract the provider's business from technology so as not to discard it in 5-10 years.

The essence of the business lies in creating a product or providing a service that meets the needs or desires of a target audience and generates profit from their sales.

Target audience

Client – partner and relationships with them, generating profit.

Solution:

#CloudRING Business

Here we build an End-to-End business

Provision of products or services (solutions)

Vendor (creation/development of products)

Provider (service provision)

Solution:

#CloudRING OpenSource

Here we create and deliver End-to-End products and services, satisfying the needs of our partners.

We are expanding the delivery channels of products and services to the fullest extent, including in the chain:

- third-party manufacturers of products and services (vendors),
- all types of businesses as partners (other providers of products and services,
- private cloud consumers,
- users of their IT infrastructures),
- sellers,
- integrators,
- agents on a non-discriminatory, mutually beneficial basis,
- all types of IT presence by location from data centers
- to developer computers.

The very definition of business hasn't become outdated in the last 100 years.

We are reinventing the cloud - how not to create an infinitely complex solution that will become obsolete.

Target audience.

Provision of products or services (solutions).

Contract

- Essential components, without which the provision of products and services is impossible (continuously improved as they develop)
- Optional components that can be done without
- As flexible as desired for everything else
- A common language of communication

Open Cloud Standard

Service Connector ensures contract-based work – an adapter for products or services into a comprehensible communication language.

#CloudRING Business

We provide everything needed for the operation of business processes in the provision of abstract products and services.

Current standard requirements for a product or service for the business service connector:

- Registration, announcement of capabilities
- Transmission of metrics on the usage of service parameters (resources)

#CloudRING OpenSource

We provide everything needed for the provision of abstract products and services and the implementation of the full life cycle.

Current standard requirements for a product or service for the service connector:

- Registration, announcement of capabilities
- Implementation of mandatory life cycle APIs
- Implementation of optional APIs if needed
- Implementation of any backend within the product API
- Implementation of any micro-frontend (within guidelines)
- Use of APIs of other products or services if needed (dependencies)

#CloudRING OpenSource

The user downloads the installer/distribution and deploys the #CloudRING OS zone on their server/servers. As a result, they have access to their #CloudRING with basic infrastructure services, development services for #CloudRING, OSS services to support the development process, and the ability to connect to the public cloud. They can receive updates from the free update channel, monitor and manage the infrastructure, and use a unified API. In the Enterprise Marketplace, they can purchase subscriptions to Enterprise services compatible with their installation, support, and other services.

Reinventing the cloud - adding innovation

Product

A full-fledged cloud (post-cloud) platform with a complete set of cloud services, separated from the cloud provider as the sole supplier for both consumption and technology creation to avoid conflicts of interest between the user and the provider.

Position

Cloud without a single provider

Paradigm

You have the same rights in development, consumption, and service evolution as other community members.

Fee

A distributed payment mechanism for services with the ability for anyone with a vendor, provider, or reseller role to earn.

Processes

Blurring the boundaries between any ways of consuming cloud technologies. Any technological achievements as services can work everywhere without restrictions. With peer-to-peer federation, you can use technologies provided by another network participant.

Global #CloudRING

Users access a unified global Cloud Portal (API, etc.), developed by #CloudRING and licensed by partner providers.

Data synchronization across the cross-provider message bus (P2P). Users can see all public clouds, territorially distributed, their private clouds (if any), EDGE, and can connect their own open #CloudRING installation.

All information about service terms, prices (in the given market), service selection options, or search by requirements (closest to me, cheapest, etc.), and unified monitoring information is available in one place.

Users can use services in all public cloud presences on #CloudRING, freely migrate between them, and pay the selected provider (who settles with others).

Cross-provider scenarios are possible (DR, replication, backup, CDN, etc.).

Cross-licensing of developed services between public providers is also possible. Revenue sharing is paid to #CloudRING and participation in the RING.

There is an opportunity to become the world's largest cloud provider without vendor lock-in.

Monetization

- All existing scenarios for cloud providers and various types of partner channels.
- Private clouds for large companies with Enterprise extensions (managing their infrastructure for products from a business standpoint to maximize infrastructure utilization). Private Cloud Extensions for integration into corporate systems and adding steps to processes. A necessary set of services from the public cloud within private infrastructure. Payment for licenses (per service, per enterprise component), for private PCE customizations, for support and maintenance (ensuring functionality in the area of responsibility, updates). Upon license expiration, functionality is preserved, but maintenance and updates for enterprise components and products (except for critical fixes, essential for ensuring future compatibility) are discontinued. The ability to connect to central clouds and purchase some services from there (which do not make sense in private) and the possibility of joint use.
- Other providers: the opportunity to build a full-fledged provider in any jurisdiction in an equal federation or without it, with payment based on a Revenue Sharing model + cost of deployment and adaptation to business specifics + cost of prioritizing customizations when necessary + cost of maintenance and support. Upon license expiration, functionality is preserved, but maintenance and updates for enterprise components and products (except for critical fixes, essential for ensuring future compatibility) are discontinued. The Revenue Sharing percentage decreases for in-house developed products and enterprise components if they are supplied on the platform with full installation or through the federated channel (depending on the volume of sales on the platform, it may drop for partner services to 0 if the partner service is profitable when sold through the main channel).
- EDGE - #CloudRING OpenSource + PCE when needed + a necessary set of services. Payment for support, maintenance, and updates. Upon license expiration, functionality is preserved, but maintenance and updates for products are discontinued. Various models: Connected (using the Business Component and Edge service in the provider and other provider services) and Disconnected without connecting to the center.
- Dev/Small: 1. Independent developers and ISVs can download and automatically deploy #CloudRING OpenSource with Compute, Network, Compute, and services where SSPL is required. Use it for service development on their own. Receive platform updates. Developer support is free, with prioritization available at an additional cost.
- For customers who are not yet ready to pay for the cloud and transition: Use developed and basic services in-house (competing with ESXI, HyperV, KVM, OpenStack – it's better to use ours), license paid services through the Service Store, connect to the central cloud and use services from there when necessary, together. Paid support is available.
